WVU IACUC SOP:  
Superovulation of female mice for embryo collection – Transgenic Animal Facility

Purpose

The purpose of this SOP is to explain the proper procedures for hormone priming female mice. Hormone priming is used to induce superovulation, thus increasing the number of fertilized embryos for use in services such as transgenic production and the rederivation and/or cryopreservation of mouse strains.

General Information

Young female mice, 3 to 6 weeks of age, are treated with hormones to induce increased follicular development and ovulation. Two hormones, PMSG (pregnant mare’s serum gonadotrophin) and hCG (human chorionic gonadotrophin) are injected intraperitoneally at timed intervals prior to mating the female with a proven stud male.

PMSG is a hormone found in pregnant mare serum that has follicle-stimulating activity. It is used to induce ovarian follicular development and oocyte maturation.

hCG is a hormone found in human placentas. As it is derived from human tissues, universal precautions should be followed when handling this substance.

1. Materials and Equipment
   a. 1 ml sterile, disposable syringe
   b. 27-gauge needle
   c. PMSG, 50IU/ml concentration, frozen -20°C in 1 ml aliquots.
   d. hCG, 50IU/ml concentration, frozen -20°C in 1ml aliquots.

2. Timing of Hormone Injections
   a. The PMSG and hCG injections should be given 46 to 48 hours apart.
   b. The PMSG injection should be given between 1 and 2pm
   c. The hCG injection should be given between 11am and 12 noon two days after the PMSG injection

3. **Recommended Hormone Dosages by Strain**

The number of embryos collected from a superovulated female mouse may be influenced by a number of factors including the strain of mouse, the age of the mouse, the dosage given, the breeding performance of the stud male, and the skill of the person giving the injection. Based on the number of fertilized embryos collected, the hormone dosage can be increased or decreased to maximize superovulation efficiencies. The hormone dosage is usually between 2.5 IU and 5.0 IU.

4. **Injection of Hormones**

   a. Hormones should be kept at -20°C until the day of use.
   b. WEAR GLOVES when handling the hormones for injection. Do not recap needles.
   c. Use a new syringe and needle for each injection.
   d. The PMSG and hCG dose for a mouse is 2.5 to 5.0 IU given intraperitoneally. Start with 5.0 IU and adjust the dosage downward, if needed.
   e. To inject a mouse with PMSG or hCG, thaw a vial(s) of 50 IU/ml PMSG or hCG at room temperature or by gently rolling the vial between your hands. Do not shake the vial.
   f. Draw 0.1ml of 50IU/ml (5IU) into a 1ml syringe with a 27-gauge needle.
   g. Restrain the mouse for an IP injection by scruffing the mouse to minimize movement. You may find that tilting the mouse slightly head downward will help as this will move the gut and bladder away from the injection site.
   h. Inject into the lower left quadrant of the abdomen. (Your left, the mouse’s lower right quadrant.) Draw back on the syringe plunger before injecting to make sure you are not in the bladder or the gut. When drawing back on the plunger, if you see yellow you are in the bladder; red, you have hit a blood vessel; brown or green you are in the gut. If this should occur discard the entire syringe. Load a new syringe and try again. Training is available from OLAR veterinary staff. Contact OLAR directly at 293-2721.
   i. Discard any unused PMSG and hCG. DO NOT RE-FREEZE.
   j. After the hCG injection on day 2, immediately place the hormone-primed female with the designated fertile stud male.
   k. Plug check the females the next morning before 9am. All females will be used for embryo collection even if a plug is not visible, as the plug may have fallen out.

5. **Generic answers for Appendix B – Non-Surgical Procedures in the IACUC protocol form**

   a. **Name of non-surgical procedure?** The superovulation of donor, female mice for embryo collection.

   b. **Provide details of the non-surgical procedure mentioned above.** To induce superovulation, donor, female mice will be hormone primed using intraperitoneal (IP) injections of PMSG, pregnant mare serum gonadotrophin and hCG, human chorionic gonadotrophin. Following the IACUC-approved protocol for the superovulation of donor females mice, the PMSG and hCG will each be given once. The hCG injection will be given 46-48 hours after the PMSG injection.
c. Indicate the approximate possible percentage morbidity and mortality due to the described procedures. Be sure to include likely causes and how they will be addressed. The intraperitoneal injection procedure utilized for the hormone priming of embryo donor females is well documented with very few clinical problems reported. We anticipate very good tolerance of the donor females to hormone priming.
